

Classification_Assignment2

1. Identify your problem statement:

A hospital management has asked to develop a predictive classification model that can predict whether a patient has Chronic Kidney Disease or not.

2. Basic info about dataset:

Total number of rows: 99

Total number of columns: 28

3. Pre-processing method:

Categorical data are converted to numerical values by label encoder

Standard scaler feature is used

4. Models performed:

I performed 6 different models and their accuracy are given as below.

Models	Accuracy
RandomForest Grid	0.99
Logistic regression grid	0.98
Decision Tree grid	0.97
Naïve bayes	0.96
SVM Grid	0.96
KNN	0.93

6. Final Model:

Final Chosen model is Random Forest Grid because its accuracy is 0.99
